C. and a viscosity of about 50 cSt at 140.degree. C. at a conversion of about 1 mole of isobutene per mole of 1-butene. Polyisobutene of this viscosity is used as an intermediate in the production of synthetic lubricants, etc. and is also used as a modifier for rubbers. The term "1-butene" as used herein is used to mean a straight-chain butene of formula CH₂=CH-CH₂-CH₃. It is reported that the above-mentioned polyisobutene is produced in the presence of a catalyst comprising a nickel salt and a phosphoric acid derivative (cf. British Pat. No. 1,227,532). However, this method is not practical since it requires a relatively large amount of catalyst and produces a large amount of sludge. Also, the conversion of the starting isobutene in the production of polyisobutene is low. The main disadvantages of this method are therefore that the catalyst is expensive and that a large amount of by-products is produced. There have also been proposed some methods in which 1-butene is polymerized in the presence of a catalyst composed of a methylaluminumoxane and a nickel compound having a bulky ligand such as a halogen atom or alkyl (U.S. Pat. Nos. 3,888,886 and 3,929,907). However, according to these patents, the amount of methylaluminumoxane used is about 10 moles, preferably about 2 moles, per mole of nickel. Thus the method is still disadvantageous since a large amount of methylaluminumoxane is used. It is therefore an object of the present invention to provide a method for the production of a polybutene which is a high molecular weight product having a boiling point of about 180.degree. C. and a viscosity of 82157476af
